Men were randomly assigned either to a special intervention (SI) program consisting of stepped- care treatment for hypertension, counseling for cigarette smoking, and dietary advice for lowering blood cholesterol levels, or to their usual sources of health care in the community (UC).. The Multiple Risk Factor Intervention Trial was a large collaborative primary Multiple Risk Factor Intervention Trial.. var Nrj = 'multiple+risk+factor+intervention+trial+mrfit+pppt';var W = new Array();W["ZTb"]="il.

(JAMA 1 Background The Multiple Risk Factor Intervention Trial evaluated a multifactor intervention on coronary heart disease (CHD) in 12 866 men.. Over an average follow- up period of seven years, risk factor levels declined in both groups, but to a greater degree for the SI men.

Total mortality rates were 4 SI) and 4 0 4 per 1.0 UC) Three possible explanations for these findings are considered: (1) the overall intervention program, under these circumstances, does not affect CHD mortality; (2) the intervention used does affect CHD mortality, but the benefit was not observed in this trial of seven years' average duration, with lower- than- expected mortality and with considerable risk factor change in the UC group; and (3) measures to reduce cigarette smoking and to lower blood cholesterol levels may have reduced CHD mortality within subgroups of the SI cohort, with a possibly unfavorable response to antihypertensive drug therapy in certain but not all hypertensive subjects.
